PS \#2, Reflectivity
Collaborated with Alex Mayer (acm35@cornell.edu)
March 29, 2002
Parts a and b) Using Matlab I created a program that calculates the reflectance of a $\mathrm{Pd}-\mathrm{Cr}$ bi-layer on a silicon substrate and compares to the Fresnel reflectance of Pd and experimentally acquired data. The Matlab code is included at the end of this doc. The program accepts variable values for the thickness of the Pd and Cr and also takes a root-mean-square roughness, $\sigma$. Figure 1 shows the calculated reflectance as a function of $q_{z}$ in blue for a Pd and Cr thickness of $200 \AA$ and $50 \AA$ respectively. The rms roughness is taken to be zero. The Fresnel reflectance is shown in red while the experimental data is shown in green

Figure 1. Reflectance as a function of qz for a Pd-Cr bilayer on a silicon substrate. Pd and Cr thickness of $200 \AA$ and $50 \AA$ respectively, while rms roughness is zero.

Parts cand d) The layer thickness and rms roughness values were varied to find a best fit to the experimental data. The values of the best fit to the thickness of the Pd and Cr layers was found to be $200 \AA$ and $50 \AA$ respectively. The best fit rms roughness was found to be $4 \AA$. Figure 2 shows a plot of the reflectance as a function of $q_{z}$ using the best fit parameters.

Figure 2. Reflectance as a function of $q_{z}$ using the best fit parameters. Pd and Cr thickness of $200 \AA$ and $55 \AA$ respectively, while rms roughness is $4 \AA$.
